

The LOFAR observatory: status, issues and recent results

Ger de Bruyn⁺

LOFAR Calibration Project Scientist

⁺ with lots of input/results from the LOFAR offline-pipeline
and commissioning teams

Outline

- The LOFAR array : overview, specs, status & images
- RFI mitigation and statistics
- Station types and (-beam) calibration
- Wide field of view and their calibration issues
- Some recent imaging results
- European LOFAR calibration ideas
- The LOFAR calibration survey: MSSS
- Conclusions

The LOFAR observatory

LBA (10) 30 - 90 MHz
isolated dipoles

| | | |
|--------|----------|--------------|
| Core | 2 km | 18+ stations |
| NL | 80 km | 18+ stations |
| Europe | >1000 km | 8+ stations |

A **station** will have 24 - 48 - 96 antennas / tiles

Principle of **Aperture Synthesis**

Array resolution: sub-arcsec to degrees

Pulsars: tied-array(s), (in)coherent sums

Sensitivity (after 4 h, 4 MHz, ~ 50 stations)

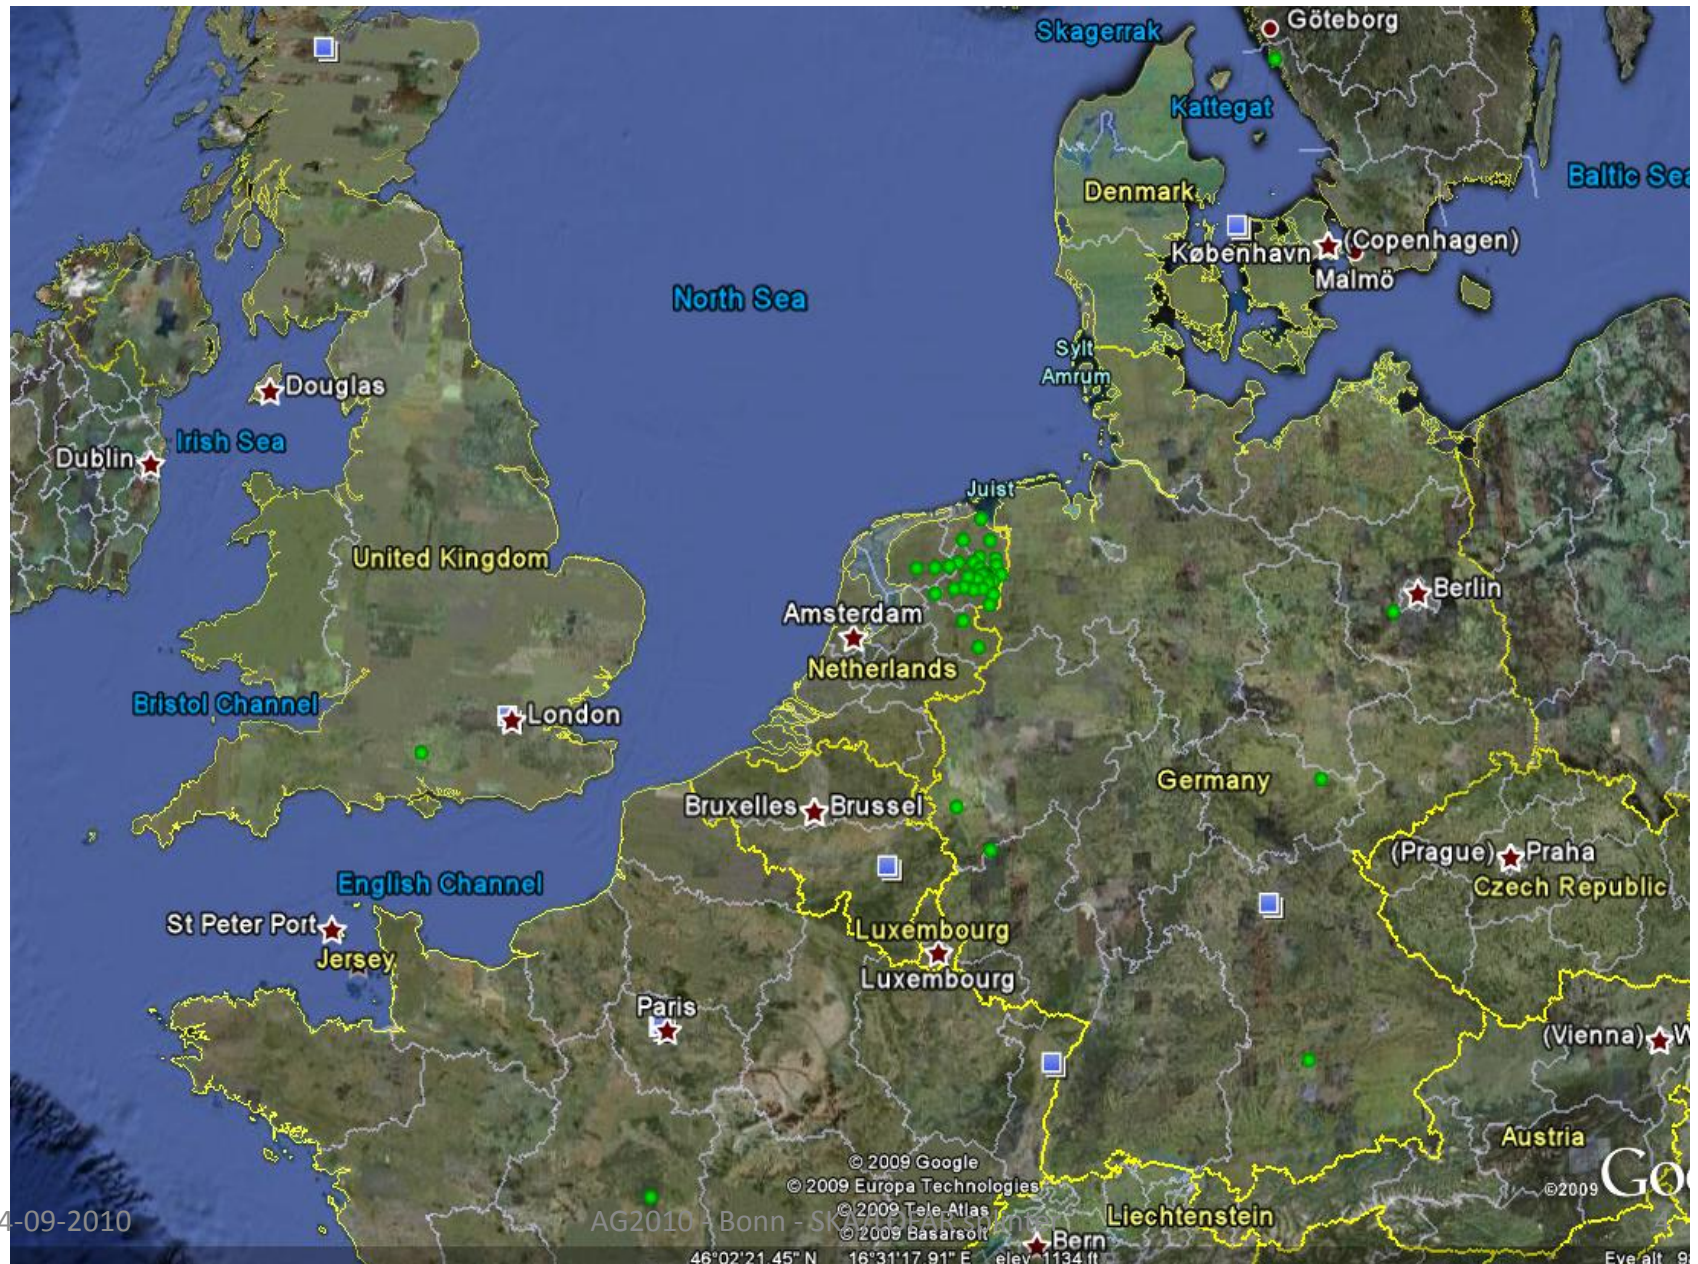

@ 60 MHz ~ 3 mJy

@ 150 MHz ~ 0.1 mJy

HBA 115 - 240 MHz
tiles (4x4 dipoles)

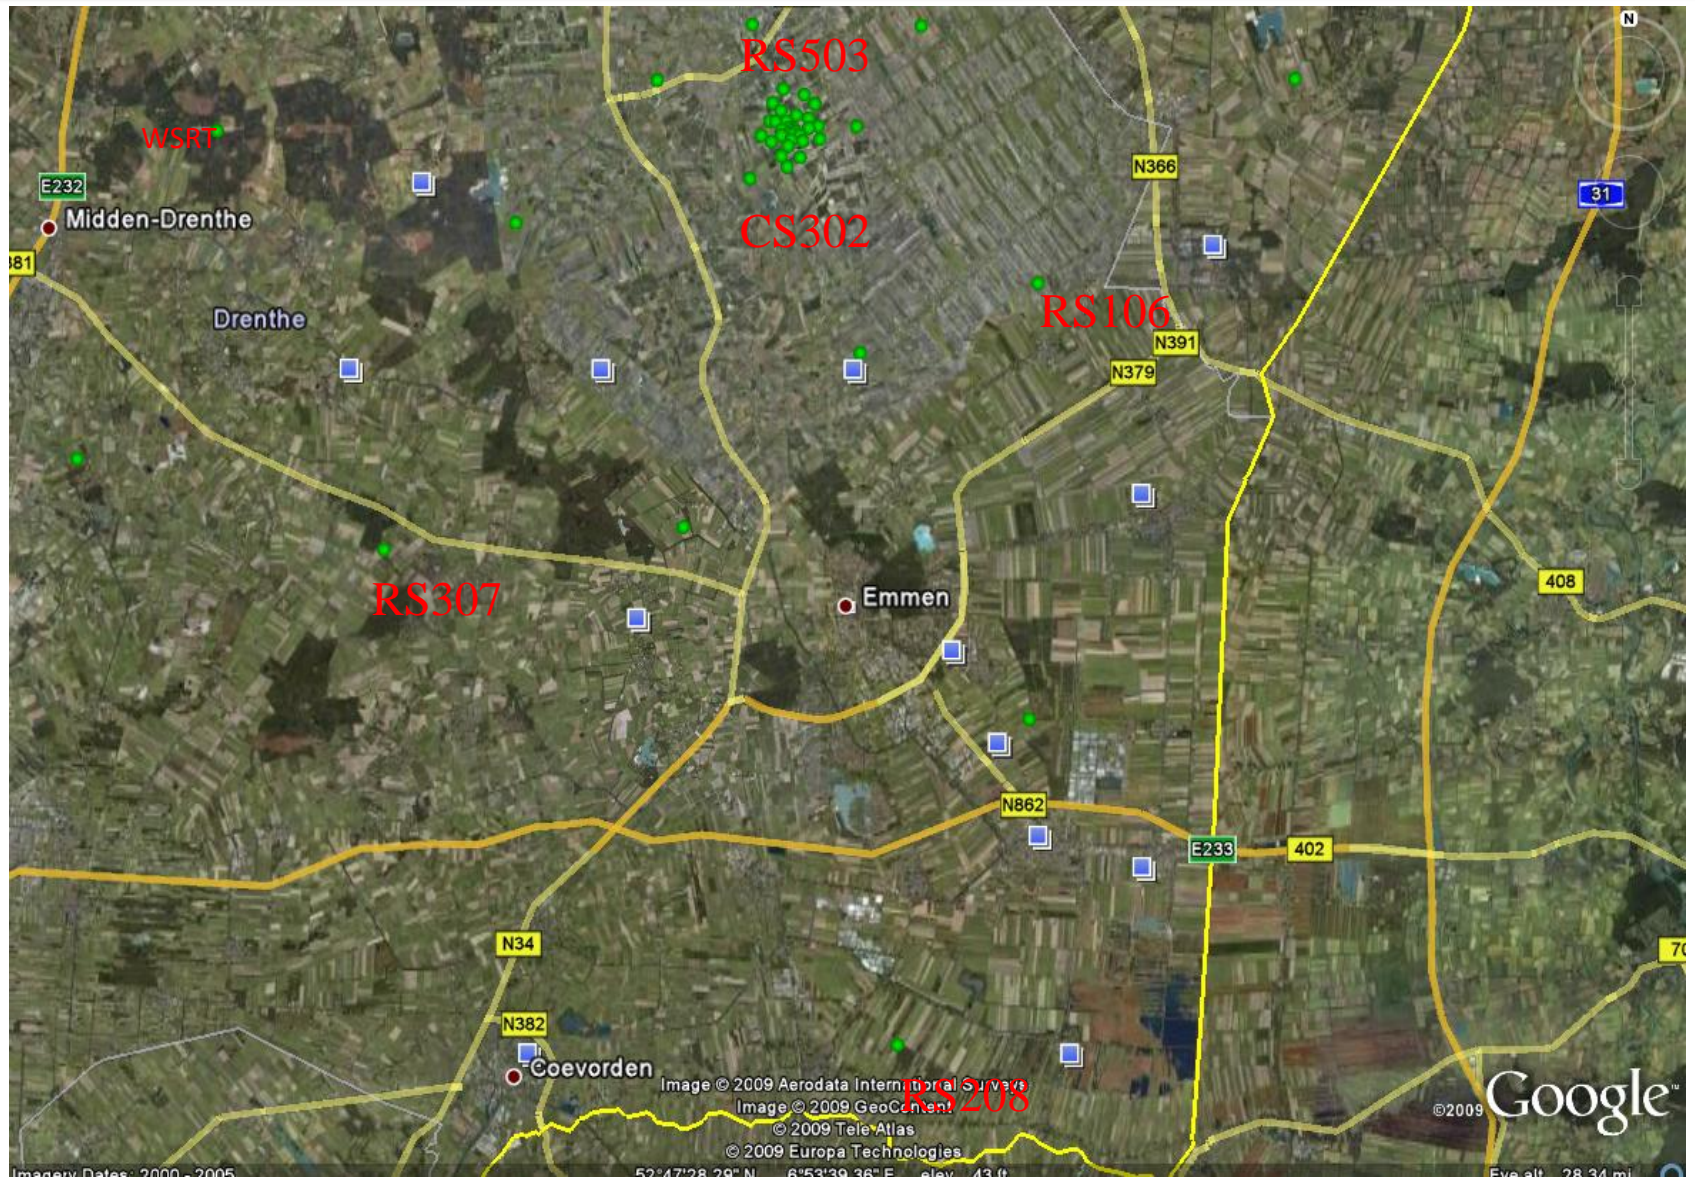

LOFAR in Europe (8+ stations)

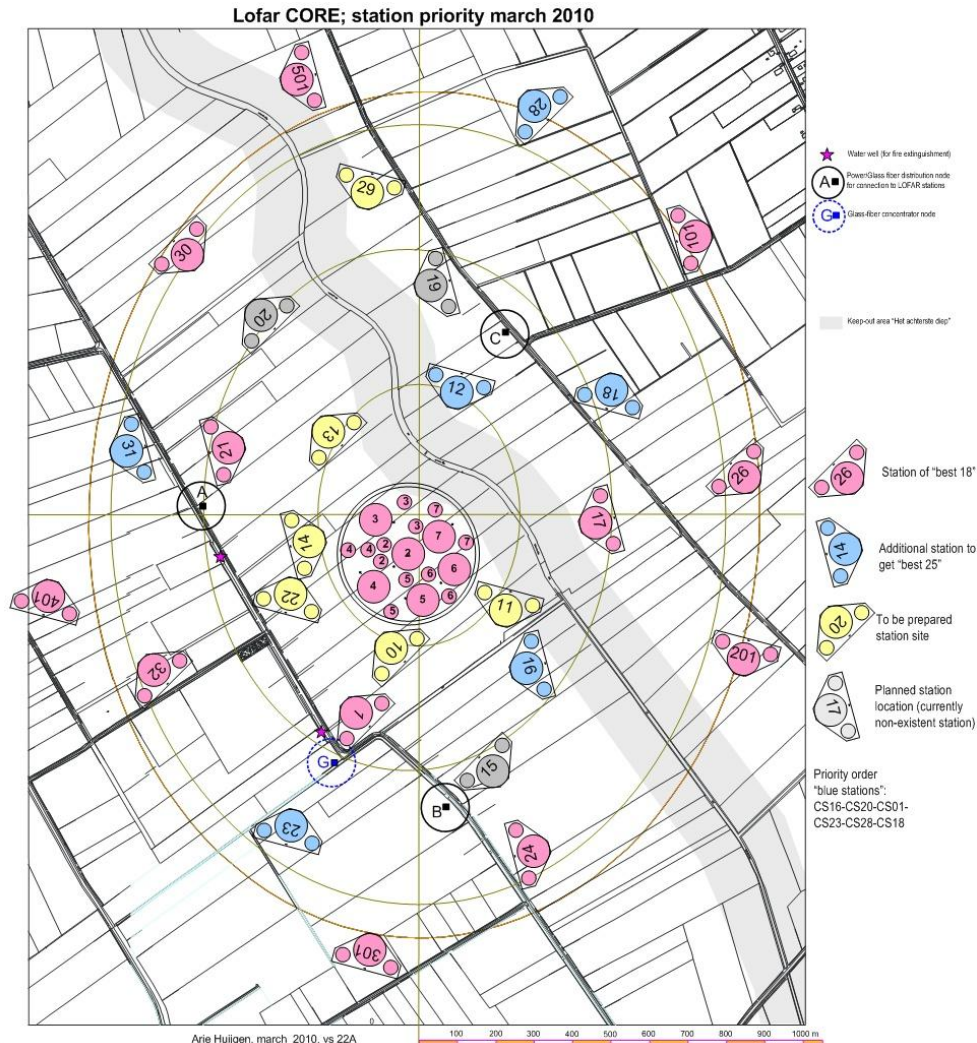

LOFAR station locations in the Netherlands

LOFAR core in South-East Drenthe

The LOFAR core area near Exloo

18 core stations
(all split-stations with
2x24 tiles)

+ 4 more stations in core
(CS011,013,028,031)

Core Stations (2x24 HBA-tiles, 96 LBA-dipoles)

International stations in Germany

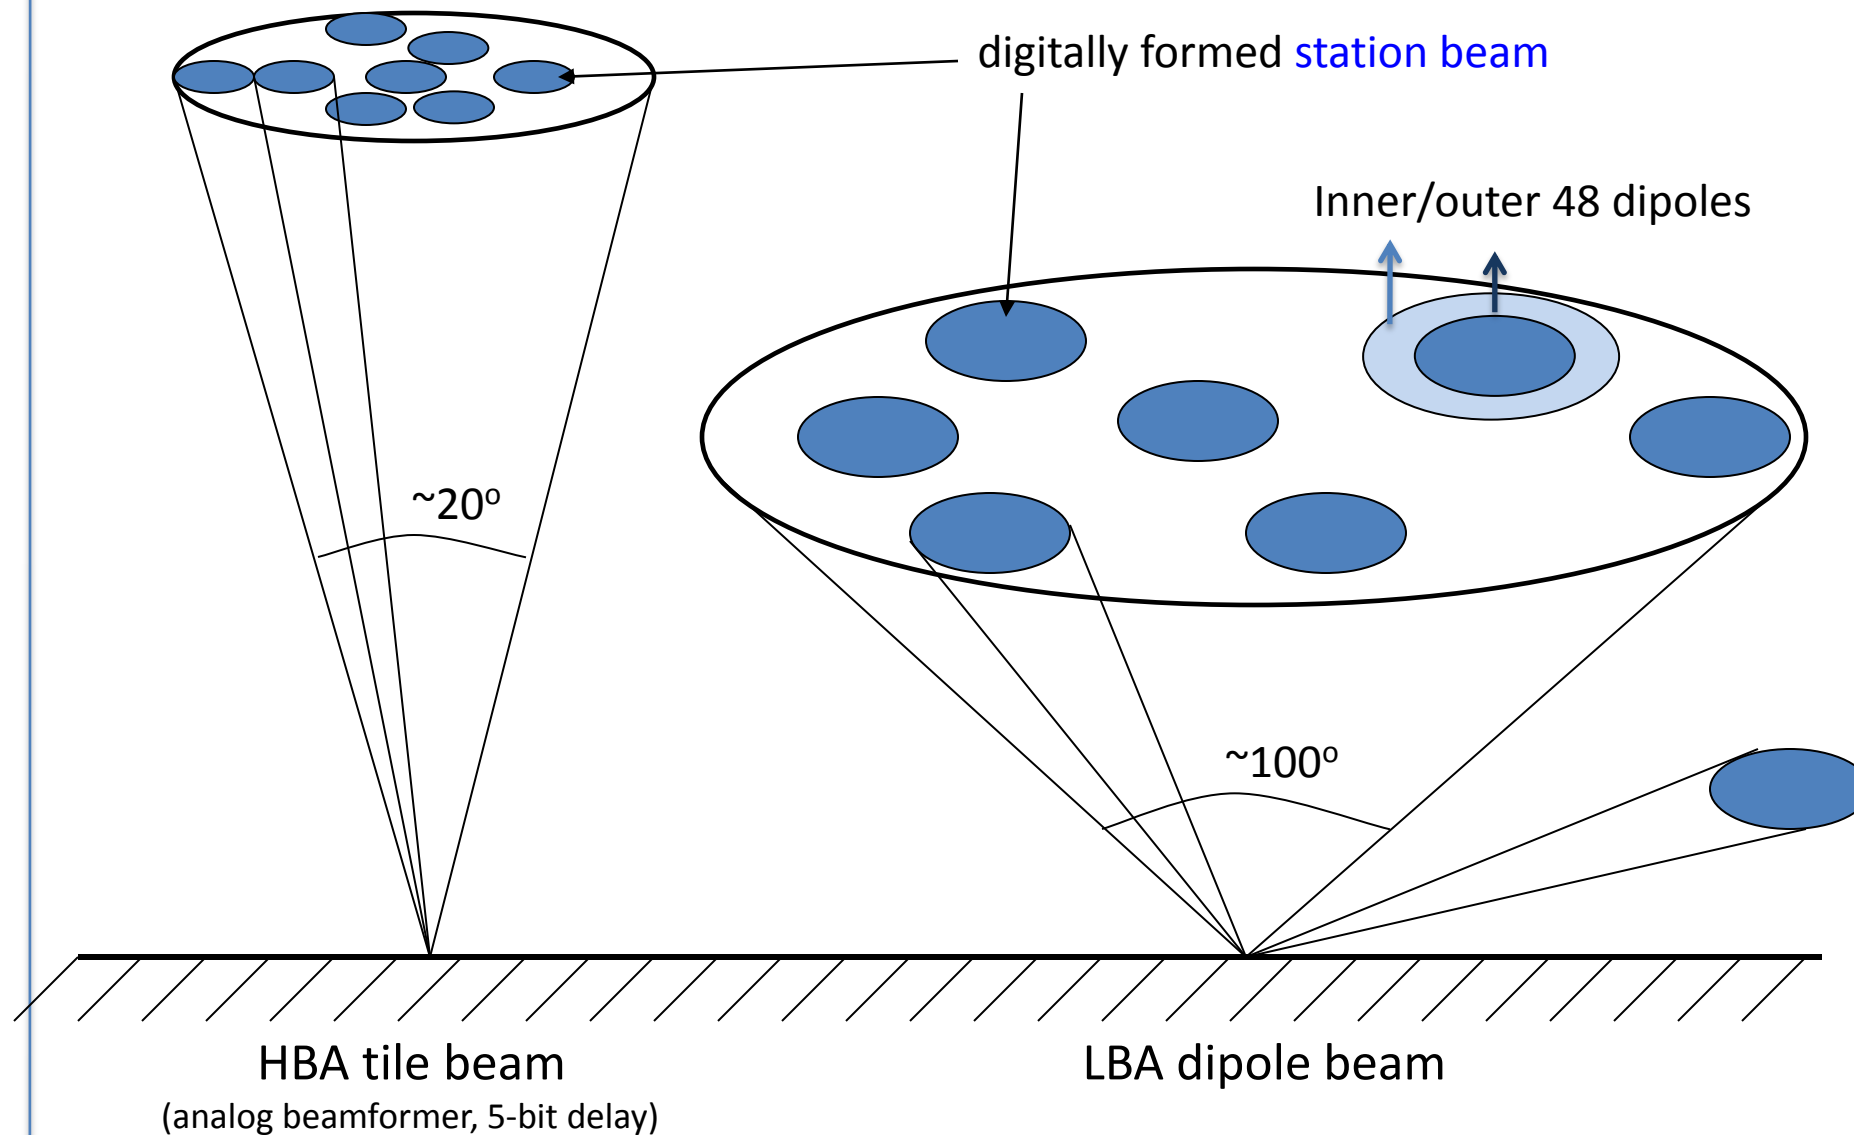

Tautenburg

96 tiles

Effelsberg

LOFARs very wide Field-of-View (good & bad !)

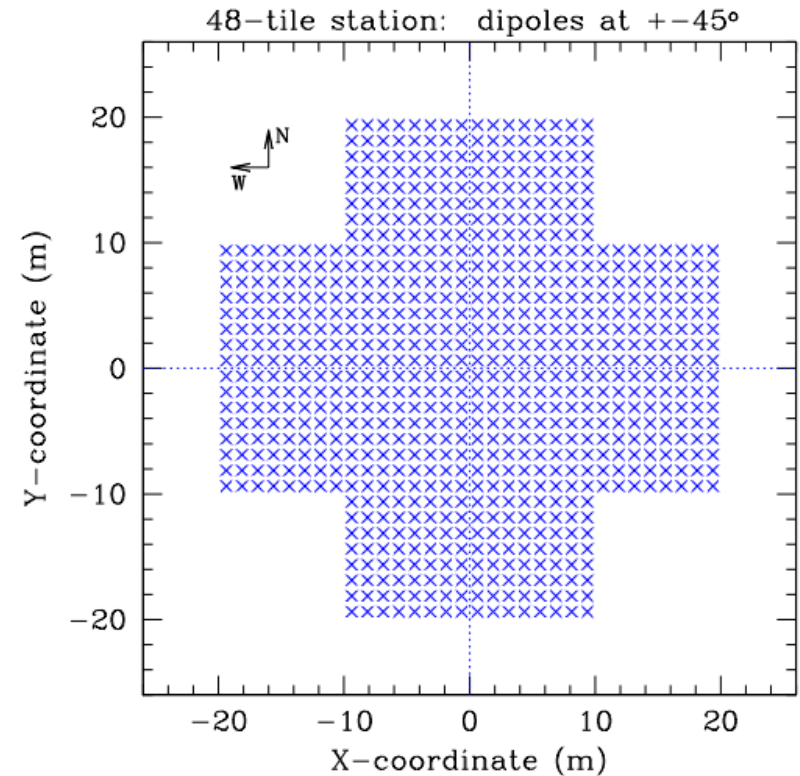

Two station sizes in NL: 24-tile (CS) and 48-tile (RS)

600 m²

~ 2000 Jy

physical area

1200 m²

SEFD (150 MHz, zenith)

~ 1000 Jy

Combating grating lobes

At frequencies > 120 MHz the tiles produce grating lobes on the other side of the sky for lowish elevations. To combat these we **rotate the stations**, and **back-rotate the antennas** within the tiles
 \Rightarrow **all dipoles remain parallel (X)**

30° rotation

LOFAR: station rollout status (preview LSM 15-Sep-10)

| Station/Item | Cabinet | LBA | HBA | Fibre | CEP connection | Validated |

Projected to be operational
in (late) Autumn 2010

24 (x2) CS Core Stations
9 RS Remote Stations
3 IS International Stations

→ 60 HBA stations

→ 36 LBA stations

→ Largest array in the world !

LOFAR calibration framework

New aspects compared to 'standard' selfcal on existing dish-arrays:

- **Major direction dependent corrections**

- Phase => 'non-isoplanaticity' of the ionosphere (low freq, wide FOV)
- Gain => elevation/azimuth dependent beamshape → **work with intrinsic sky models !**

- **All-sky calibration, very wideband synthesis and imaging**

- Global Sky Model needed (spectral index, structural parameters, polarization)
- w-term always very important (w-projection, speed issue)

- **Full-polarization Measurement Equation (Hamaker, Bregman & Sault, 1996)**

(Jones matrix description: B, G, E, I, F : 2x2 matrices, both complex and scalar)

e.g. Bandpass, electronic **G**ain, beam (**E**-Jones) , Ionospheric refraction, Faraday rotation

Developed largely in- house: Bregman, Hamaker, Noordam, Brouw, de Bruyn, Wijnholds, Yatawatta, Brentjens, Nijboer, ... + Leiden ionospheric group (Rottgering, Intema, van der Tol)

LOFAR has superb frequency resolution

Two 12-bit ADC sampling modes: 200 MHz and 160 MHz clock

Frequency filtering done in two digital (Poly-Phase-Filter) stages:

- at station \Rightarrow 512 subbands (either 156 or 195 kHz)
- at CEP (BG/P) \Rightarrow 256 channels for each of 248 subbands split

RFI & wide-field VLBI
(+ 21cm & rec lines)

48 MHz total bandwidth

63,488 channels of 0.8 kHz !

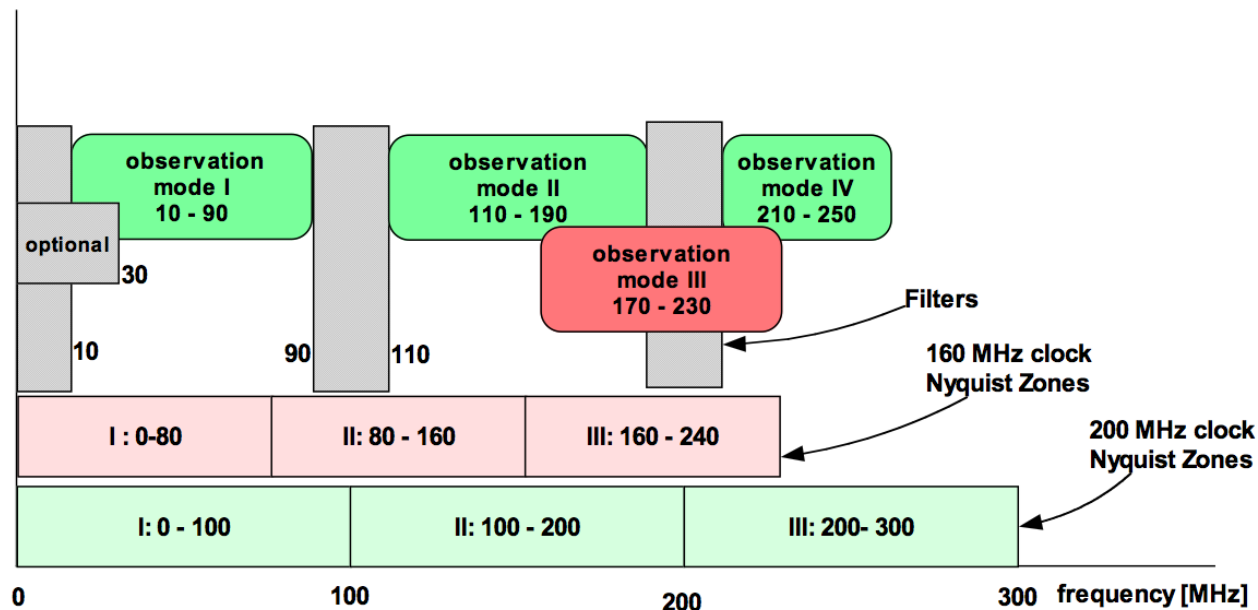

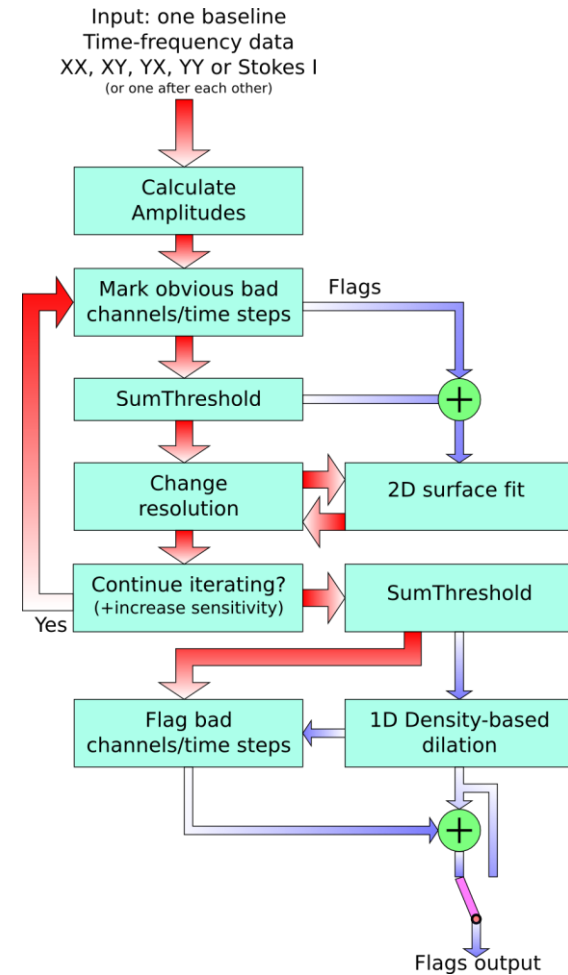

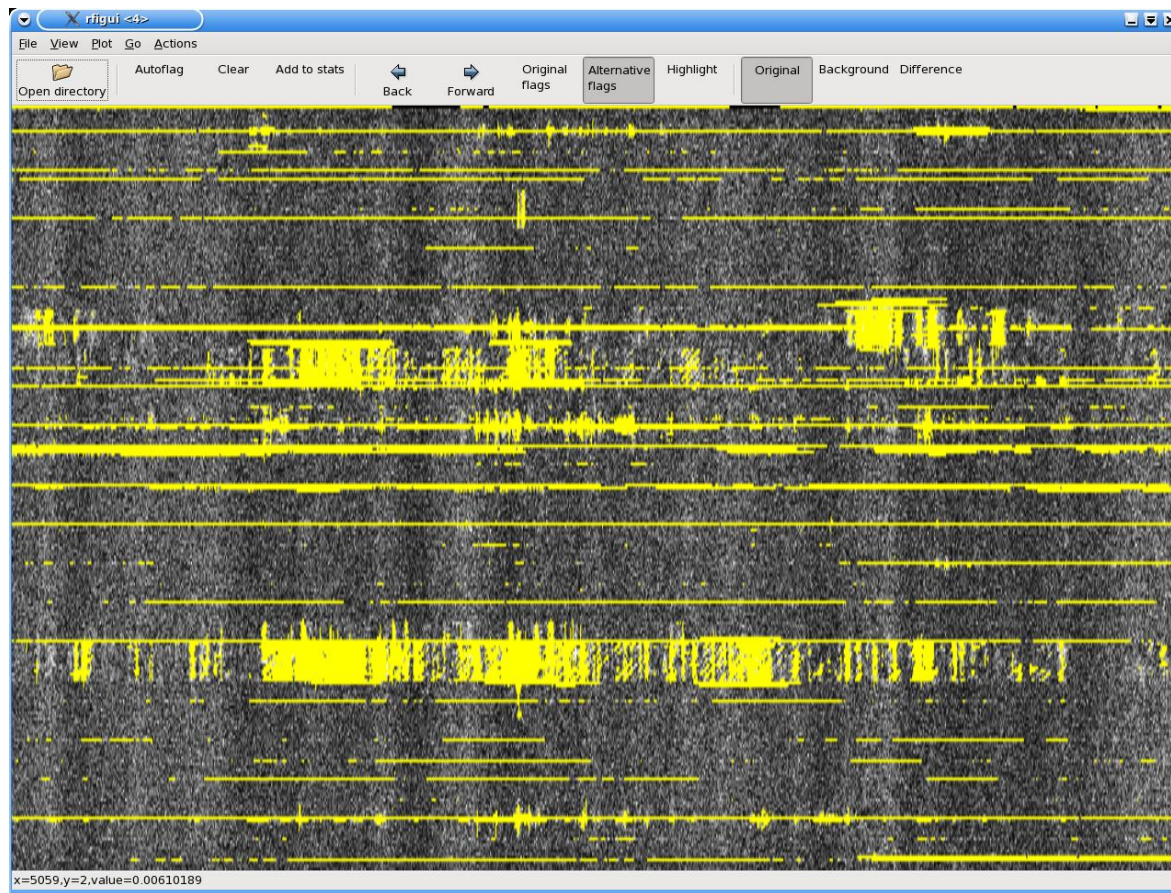

Figure 10 Selection of Nyquist zones is used to select the observed band in the station.

WSRT data around 145 MHz

AO-flagger performance on LOFAR data

LOFAR RFI pipeline

A.R. Offringa

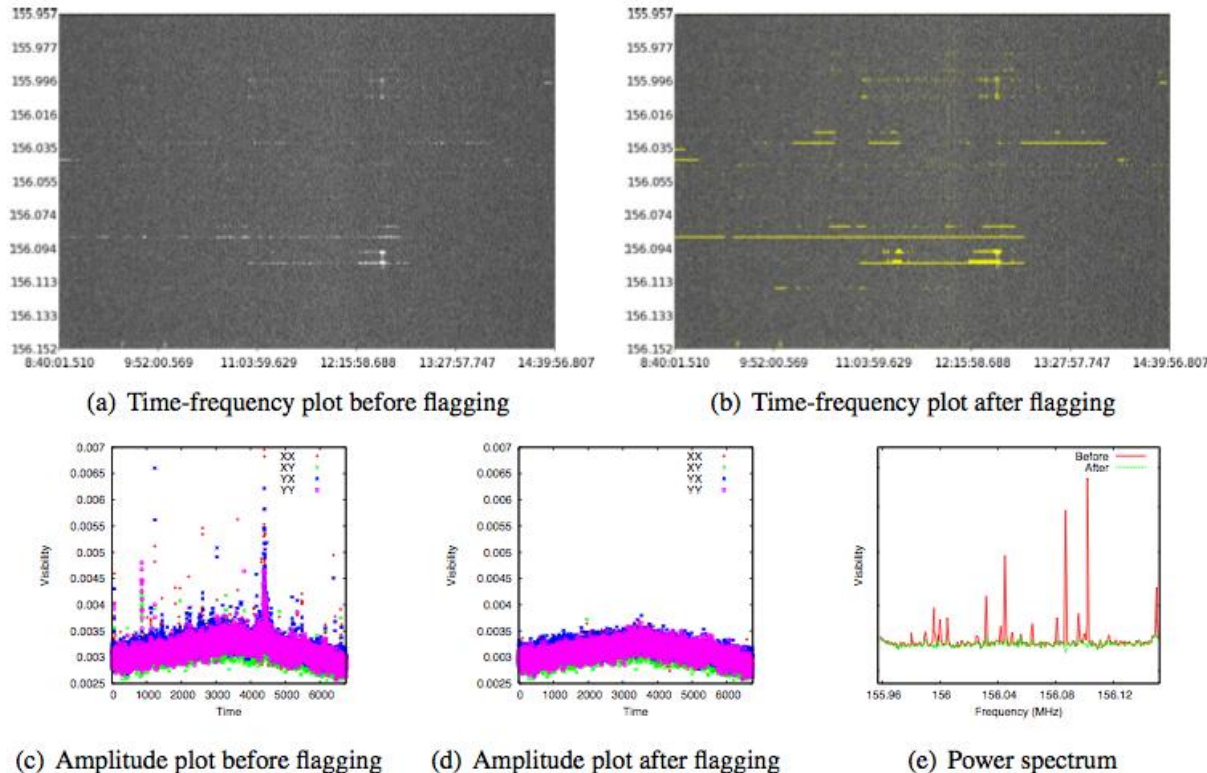

Figure 3: Flagging results of the 6 hour LOFAR observation L2010_07096 of April 24, 2010. All plots show the same sub-band around 156 MHz for baseline CS302_HBA1 \times CS005_HBA0 with one second integration time. The flagging pipeline was run with its default settings, and 1.8% of the data is flagged. As can be seen from panels (a), (c) and (e), this sub-band contains relatively many interfering transmitters, yet all of them are relatively weak. The panels (b), (d) and (e) show the cleaned band after flagging.

Some recent LOFAR hw/sw developments

Station calibration algorithms/procedures ready for implementation

Rapid increase in # stations from $10 + 5 + 1$ to $15 + 7 + 3$ (target $22 + 18 + 8$)

All 6 stations on the superterp share the same clock (\rightarrow coherent addition)

Multi beam (5 !) observations on 3C196

Offline cluster: 8 subclusters each with 9 nodes x8 cores

Parallellized pipeline processing

After switch from 16-bit to 4-bit transport:

Future 48MHz-beams \rightarrow 192MHz-beams throughput

Limited by ~ 50 Gbit/s output/storage

Station calibration procedures:

2.4 Fish-eye imaging

Wijnholds, thesis mar10

29

LBA station calibration via
Least Squares Intensity Mapping
using the whole sky (not just
CasA and CygA)

Gain loss due to ill alignment of phasors

15% loss @110MHz, increasing to 40% @180MHz

HBA station calibration via intra-
tile redundancy calibration

Currently still poor 'alignment',
'collimation', 'focusing'

LOFAR Status Meeting, Dwingeloo, 9 December 2009

Polarized Double-Double Radio Galaxy B1834+620 ~ 150 MHz, ~ 10 km array

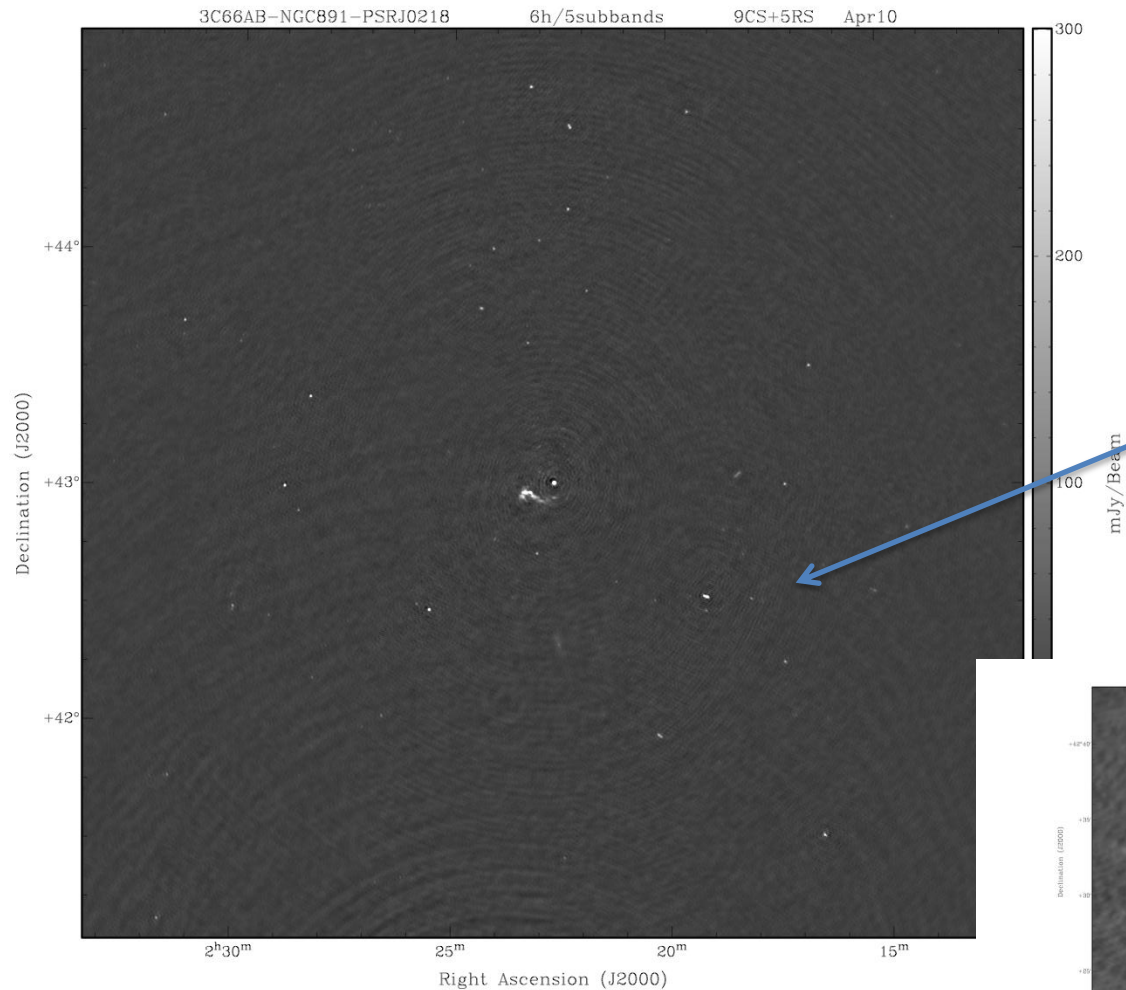

Poster Jana Köhler et al.

Simultaneous pulsar timing + imaging: PSR0329+54

Jason Hessels et al

PSRJ0218+4232

 $S_{150\text{MHz}} \sim 500 \text{ mJy}$

50% linearly polarized

3C61.1 close to North Celestial Pole (elev=53°)

8° x 8°
7200x7200 pixels
10" PSF

60h 20-22 Dec 2009
14 MHz bandwidth
8 CS + 4 RS

Only brighter 100
sources deconvolved

Sarod Yatawatta

Inner
 $1.7^\circ \times 1.7^\circ$

50 sources per
square degree
>10 mJy

Still poor
'cup-saucer'
PSF

Noise level ~ 0.6 mJy
(only factor ~ 3 away from thermal noise)

3C 61 peak 10 Jy \rightarrow DR $\sim 15000:1$

Remaining artefacts in this deepest LOFAR image (with only ~ 12 stations) are due to:

- 1) Sidelobes very distant sources
- 2) Very poor station beampatterns
- 3) 3 sizes for interferometer beampatterns
- 4) Deconvolution issues on 3C61.1, causing ripples across field

Ionospheric TEC modeling

- 1) Both **refraction and Faraday rotation** depend on **absolute TEC** which changes relatively slowly with time and direction
- 2) **Selfcalibration/imaging** depend on **relative TEC** which varies rapidly (1-10s) --> selfcal/peeling takes (partly) care of this
- 3) Ways to measure absolute TEC:
 - Monitor differential refraction across wide angles
 - Observe Faraday rotation (FAN-region, pulsars)
 - Use GPS data
 - Use snapshot all-sky observation sequences (e.g. 10s every 120s) and combining absolute+relative delays

Observing a (polarized?) pulsar in the LBA band

/dop64_3/ger/LOFAR/6stat/data/15oct09_L15362/SB24/SB24.MS Spectral Window: 1 Polarization: 1 Field
XX YY Antenna1 = 2 Antenna2 = 4

35 MHz

SNR ~ 3 (in 180 kHz, 3s)

Assuming station SEFD is about
25,000 - 50,000 Jy

/dop64_3/ger/LOFAR/6stat/data/15oct09_L15362/SB80/SB80.MS Spectral Window: 1 Polarization: 1 Field
XX YY Antenna1 = 2 Antenna2 = 4

45 MHz

The estimated flux of the pulsar
must then be about 150 - 350 Jy
(to within a factor ~ 2)

/dop64_3/ger/LOFAR/6stat/data/15oct09_L15362/SB144/SB144.MS Spectral Window: 1 Polarization: 1 Field
XX YY Antenna1 = 2 Antenna2 = 4

56 MHz

Fluxes still uncertain because of
unknown station gain and
skynoise

European baselines: non-overlapping screens !

Basic problems of wide-FOV European LOFAR:

- 1) isoplanatic patch small ($\sim 3\text{-}15'$)
- 2) $\sim 10\times$ fewer calibrator sources
- 3) non-overlapping screens
- 4) large datavolumes (0.2s, 1 kHz?)

A possible solution (for HBA)

- 1) solve for NL screen in NL-LOFAR
- 2) correlate $\sim 10\text{-}20$ **superterp tiedarray beams** with each Eu-station (sensitivity $\sim 10\times$ better)
- 3) dynamically track the screen motion using > 20 probes
- 4) NB: 30s x 600 km/h ~ 5 km $\sim 1^\circ$ at 300 km height

'default' mode for EoR KSP on much smaller scales ('rapid' all-sky calibration mode)

European calibration issues (HBA 150 MHz)

| #antennas | noise (Jy) | FOV |
|------------------------------|--------------------|------------|
| | (10s,15 MHz, 2pol) | (HPBW,deg) |
| Eu96 - NL48 (65m - 40m) | 0.07 | 2.3x3.7 |
| Eu96 - ST288 (65m - 300m) | 0.03 | 2.3x0.5 |

Required on line:

- known positions to attempt correlation, or coherent addition of complex 0.2s visibilities, using ST6 ionospheric screen)
- global TEC model to predict refraction

Summary of current commissioning issues

Final verification of single-clock superterp (benefits VLBI work)

Validating station calibration ('beamserver')

Parametrization of station beams

Streamline multiple/simultaneous direction-dependent BBS solution

Apply direction-dependent errors (beams/ionospheric screen)

Further integration of all pipeline components

Compare ionospheric TEC solutions with Faraday rotation data on selected pulsars

Prepare for the northern sky calibrator survey: MSSS (next slide)

The LOFAR Million Source Sky Survey (MSSS)

LOFAR needs a *Global Sky Model (GSM)* for the northern sky which

- has a proper flux scale
- has validated (initial) source parameters (spectrum, structure, ..)
- is astrometrically correct to better than 0.5''
- interfaces efficiently to calibration & imaging pipeline (through the LSM)

This survey will take about 3 months at 50% efficiency and should deliver about 1 million sources.

Carrying out MS³ will also

- create a *joint focus for activities*
- integrates scheduling, monitoring, processing, calibration & imaging
- test all KSP-pipelines
- provides a field-test for storage and processing resource needs
- will be a dress-rehearsal of full LOFAR operations

Conclusions

- Imaging wide fields with 30 km baselines down to 30 MHz achieved
- Sub-mJy noise levels reached in HBA band (115-185 MHz)
- DR ~ 15000 achieved in 3C61.1 field (dec $=+86^\circ$) and 3C196 (dec $=+48^\circ$)
- Very wide field images (>5 degrees) (still benign ionosphere)
- European LOFAR scale imaging successfully conducted
- Scheduling(SAS), monitoring (MAC), multi-beaming and multi-application integrated

Current LOFAR dynamic range still limited (factor 10 from noise) because of:

- 1) Uncalibrated (=unfocused) stations beams
- 2) Still not very good snapshot uv-coverage (rapidly getting better)
- 3) 6 different effective HBA-beams (24-24, 48-48, 24-48, 96-96, 24-96, 48-96)
- 4) No application of direction-dependent effects (DDEs) as yet

MSSS calibration survey expected to start in the Autumn 2010

Lots to do, Stay tuned , watch the AJDI (Astron Jive Daily Image)
