Outline	Introduction $^{\circ}$	HIRLAM 000	Raytrace approach O	Moritz approach 0000000000	Conclusions
Introdu	ction				

- An important limitation for the precision in the results obtained by space geodetic techniques like VLBI and GPS are caused by the tropospheric effects due to **neutral atmosphere**
- In recent years numerical weather models (NWM) have been applied to improve mapping functions which are used for tropospheric delay modeling in VLBI and GPS data analyses
- A troposphere correction model based on direct calculation of the slant delay applying raytracing to the **Conformal Theory of Refraction** through the Limited Area numerical weather prediction (NWP) HIRLAM 3D-VAR is developed
 - The advantages of the Conformal Theory of Refraction is that the atmospheric propagation effects are evaluated along the *line of sight* and the known *vacuum elevation angle* is used so no iterative calculations are needed
 - The advantages of HIRLAM model are the high spatial resolution (0.2°×0.2°) and the high temporal resolution in prediction mode (every 3 hours)

Moritz approach

Refractivity: curvature and delay

Electrical path length $L(\epsilon, \phi) = \int_{S} n ds$

S: path of the signal G: geometrically shorter path Atmospheric delays can be evaluated along the path of the ray originating from the direction of the ray emission source and passing through the atmosphere to a receiving antenna

Path delay

$$\Delta L = 10^{-6} \int_S N(s) ds$$

HIRLAM: High Resolution Numerical Weather Model (NWM)

- Limited Area Model (Europe)
- Synoptic scale (displaying conditions simultaneaously over a broad area)
- Hydrostatic grid point model
- Spatial resolution $0.2^{\circ} \times 0.2^{\circ}$
 - Horizontally: 22 to 5 km
 - Vertically: 16 to 60 levels
- Temporal resolution
 Analysis: 6 hours assimilation cycle (00h, 06h, 12h, 18h)
 Forecast: every 3 hours
- Initial and boundary conditions:
 ECMWF (European Centre for Medium-Range Weather Forecast)

Davis, J.L., T.A.H. Herring and A.E. Niell, The Davis/Herring/Niell Raytrace program, 1987-1989

HIRLAM input:

- Profiles 6 hours time resolution (00h, 06h, 12h, 18h)
- 22 km horizontal resolution
- 40 vertical levels refine to approx. 1000 layers
- Atmosphere height extrapolated to 136 km
- Grid model: interpolation between the 4 nearest points around the station

Raytrace program:

• Pressure, Temperature and Relative Humidity profiles at a starting height above sea level for each site and time epoch

= 900

- Elevation angle of each observation
- No Azimuth angle dependence
- Calculate 'Path Delay' through the homogeneous atmosphere

Application of the Conformal Theory of Refraction

Moritz approach

Outline Introduction HIRLAM Raytrace approach Moritz approach Conclusions 0 000 0 0 0 0 0 0

Application of the Conformal Theory of Refraction (I)

Derived by Moritz (1967) and developed by Brunner and Angus-Leppan (1976)

- Solution of Eikonal equation has been included in the equations
- Atmospheric propagation effects are evaluated along the **known chord line** and not along the unknown wave path
- Vacuum elevation angle is used so no iterative calculations are needed

= 900

$$\Delta S = 10^{-6} \int_0^S N dX - \frac{1}{2} 10^{-12} \int_0^S \left[\left(\int_0^S \frac{dN}{dY} \varepsilon d\varepsilon \right)^2 + \left(\int_0^S \frac{dN}{dZ} \varepsilon d\varepsilon \right)^2 \right] \frac{dX}{X^2}$$

where ε is a integration variable only

If we neglect the small effect of curvature due to lateral refraction caused by $\frac{dN}{dY} \approx 0$, and $\frac{dN}{dZ} = \cos\beta(\frac{dN}{dh})$ where β is the vacuum elevation angle.

Then practical approximation:

$$\Delta S = 10^{-6} \int_0^S N dX - \frac{\cos^2 \beta}{2} 10^{-12} \int_0^S (\int_0^S (\frac{dN}{dh}) \varepsilon d\varepsilon)^2 \frac{dX}{X^2}$$

 Moritz approach (I)

 HIRLAM input

Interpolation in time

• Profiles 6 hours time resolution (00h, 06h, 12h, 18h): interpolation in time for each scan

Interpolation in the horizontal

- Grid model: 22 km horizontal resolution
- Interpolation between the 4 nearest points around the station and each ray point in the atmosphere (check if it is in the same vertical profile)

Interpolation in the vertical and refinement

- 40 vertical levels refine to approx. 1000 layers (step size depend on atmosphere height)
- Atmosphere height extrapolated to 136 km
- Station height in the HIRLAM vertical profile (interpolation/extrapolation)
- Heights calculated over WG84 ellipsoid and undulations from potential coefficient model egm96

Not in scale! Courtesy: Carolina ZG - 3dmax 2010

- Elevation angle of each observation
- Azimuth angle dependence
- Neglect the small effect of curvature due to lateral refraction caused by $\frac{dN}{dY}\approx 0$
- Starting integration at station height
- Size and number of integration steps along the chord line depend on vacuum elevation angle β and the current height of the ray point in the atmosphere (vertical refinement steps). Need to find a compromise with execution time (approx. 250 integration steps)
- Recalculate β at each ray point
- Calculate 'Path Delay' through the **3D inhomogeneous atmosphere** through the chord line

Forecast and analysis HIRLAM profiles are combinated Differences between HIRLAM comparison are due to improvements in interpolation (distance calculation) Mean = 0.83 mmStandard deviation of the mean = 0.02 mm

Conclusions and Future work								

Conclusions

- We have calculated slant delays using homogeneous and inhomogeneous atmosphere
- Raytrace approach simplifies to an homogeneous atmosphere
- Moritz approach includes the effect of an inhomogeneous atmosphere in the delay
- Differences between Raytrace and Moritz approach are the inhomogeneous atmosphere contributions
- Comparison of ZWDs and slant delays at elevation 90° using Moritz approach is in the order of 1 mm level due to improvements in the interpolation
- We calculate more precise and accurate slant delays with Moritz 3D approach

Future work

- Comparison of Moritz slant delays raytrace through HIRLAM to other NWM e.g. ECMWF and other approaches e.g. KARAT
- We will analyze VLBI European data using the calculated slant delays as apriori
